Main subroutine

The screenshot below shows the main function, we can see this is a quite basic main function that only calls 1 function GetRemoteProcessHandle() which we will reverse next before we continue with the rest of the main() subroutine.

First it's going to start with the prologue, making space onto the stack for the parameters/variables.

The main function will load the handle to the process, and handle to the PID. In order to know what will happen when those parameters are provided we have to dive into the GetRemoteProcessHandle() subroutine.

```
; int __cdecl main(int argc, const char **argv, const char **envp) main proc near
         rsp, 40
                           ; eax hold 0
         r8, [rsp+28h+hProcess]; void **
lea
              [rsp+28h+Pid] ; unsigned int '
         [rsp+28h+Pid], eax; moves eax register into memory location by offset 28 also add the value of Pid to RSP (Stackpointer)
[rsp+28h+hProcess], rax; moves rax register into memoryby offset 28, add value of hProcess to RSP
                                rax ; moves rax register into memoryby offset 28, add value of hProcess to RSP
call
       GetRemoteProcessHandle
         short loc_14000130C
jnz
                                                                4
                                   add
                                                                loc 14000130C:
                                                                         r8d, [rsp+28h+Pid]
                                   retn
                                                                mov
                                                                lea
                                                                         rcx, aFoundSOfPidD; "[+] FOUND \"%s\" - Of Pid : %d \n
                                                                lea
                                                                         wprintf
                                                                         rcx, aPressEnterToQu ; "[#] Press <Enter> To Quit ...
                                                                 call
                                                                         printf
                                                                         cs:__imp_getchar
                                                                add
                                                                 main endp
```

GetRemoteProcessHandle

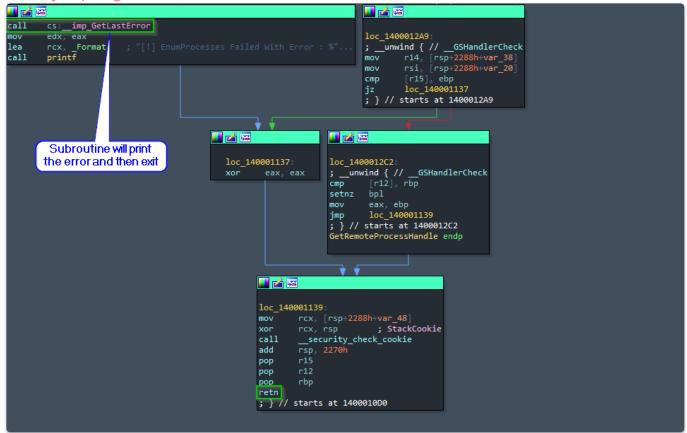

The function is going to make a call to EnumProcess which allows the program to gather processes that are present on the target machine.

```
🛮 🚄

Seeking to Find Target Process

It irates over each process, with full access. After that the it will gather GetModuleBaseName() because that is required by the next called WinAPI.

```
